

# Diabetes Update

Elys M. Perez, MD

Department of Endocrinology, Diabetes, and Metabolism

Broward Health Medical Center

# Conflict of Interest

- ▶ I have no conflict of interest to report

# Overview

- ▶ Clinical practice in the patient population with diabetes
- ▶ Classification and diagnosis
- ▶ Prevention or delay of type 2 diabetes
- ▶ Assessment of comorbidities and management
- ▶ Glycemic targets
- ▶ Pharmacologic approaches to glycemic treatment

# Diabetes and Population Health

- ▶ Treatment recommendations should follow current evidence-based guidelines
- ▶ Tailored to every individual patient based on patient preference, prognosis and comorbidities
- ▶ According to a 2013 report, 33-49% of patients still did not meet general targets for glycemic, blood pressure, or cholesterol control
- ▶ Only 14% met targets for all three measures and smoking cessation
- ▶ Economic costs of diabetes have increased by 26% from 2012-2017

# Chronic Care Model

- ▶ Proactive care delivery system with a team based approach
- ▶ Self-management support
- ▶ Basing care on evidence based guidelines
- ▶ Using registries that provide patient-specific and population-based support to the care team
- ▶ Identifying or developing resources to support healthy lifestyles

# Classification and Diagnosis

- ▶ Type 1 diabetes
- ▶ Type 2 diabetes
- ▶ Gestational diabetes
- ▶ Other (monogenic diabetes syndromes, diabetes secondary to diseases of the exocrine pancreas, drug induced)

# Screening

- ▶ Test adults with a BMI  $\geq 25$  or  $\geq 23$  in Asian Americans who have any of the following risk factors
  - ▶ 1° relative with diabetes
  - ▶ High risk race/ethnicity
  - ▶ History of CVD
  - ▶ HTN
  - ▶ HDL  $\leq 35$  or triglycerides  $\geq 250$
  - ▶ PCOS
  - ▶ Physical inactivity
  - ▶ Severe obesity or acanthosis nigricans
- ▶ For all people testing should begin at age 45

# Diagnosis

FPG  $\geq$  126 mg/dl

OGTT  $\geq$  200 mg/dl at 2 hours (after the administration of 75g of glucose)

A1c  $\geq$  6.5%

RPG  $\geq$  200 mg/dl in patients with classic symptoms of hyperglycemia

# Prevention and Delay

- ▶ Annual monitoring is suggested for those with prediabetes
- ▶ All patient should be referred to an intensive lifestyle intervention program at diagnosis of prediabetes or diabetes
  - ▶ Aim to achieve and maintain 7% loss of initial body weight
  - ▶ Increase moderate-intensity physical activity to 150min/week
  - ▶ In the DPP, diabetes incidence was reduced by 58% over 3 years
  - ▶ The diabetes prevention program outcomes study has shown sustained reduction in the rate of conversion to type 2 diabetes of 34% at 10 years and 27% at 15 years
- ▶ Pharmacologic therapy with metformin should be considered for those with prediabetes and:
  - ▶ BMI  $\geq$  35
  - ▶ Age < 60 years
  - ▶ Women with prior GDM

# Assessment of Comorbidities

- ▶ Consider screening patients with type 1 diabetes for autoimmune disorders
- ▶ In patients with cognitive impairment treatment goals should aim at avoiding hypoglycemia
- ▶ Evaluate the need for diabetes self management education and support (DSMES) at diagnosis, annually, when complications arise, and during transition of care
- ▶ Refer all patients for medical nutrition therapy (MNT)
- ▶ Assess patients for symptoms of diabetes distress, depression, anxiety, disordered eating and cognitive capacities

# Blood Pressure

- ▶ Aim to maintain blood pressure < 140/90 mmHg for patients with diabetes
- ▶ For those patients with ASCVD > 15%, aim for a target blood pressure of < 130/80 mmHg
- ▶ ACE-I or ARBs are the recommended first line therapy

# Lipids

- ▶ For patients with diabetes and ASCVD, if LDL cholesterol is  $\geq 70$  mg/dl on maximally tolerated statin therapy consider adding additional LDL-lowering drugs such as ezetimibe or a PCSK9 inhibitor

# Cardiovascular Disease

- ▶ In patients with ASCVD consider use ACE-I or ARBs to reduce risk
- ▶ Those with type 2 diabetes and established ASCVD using SGLT2 inhibitors or GLP-1 receptor agonists with proven benefit is recommended
  - ▶ In those with heart failure or high risk of heart failure SGLT2 inhibitors are preferred

# Microvascular Complications

- ▶ Chronic kidney disease
  - ▶ Check urine albumin to creatinine ratio (UACR)
    - ▶ In patients with type 1 diabetes 5 years after diagnosis and then yearly thereafter
    - ▶ In all patients with type 2 diabetes
    - ▶ In all patients with hypertension
  - ▶ ACE-I or ARBs are recommended in patients with hypertension and UACR between 30-299 mg/g creatinine
  - ▶ For patients with type 2 diabetes and CKD use a SGLT2 inhibitor or a GLP-1 receptor agonist

# Microvascular Complications

- ▶ Diabetic retinopathy

- ▶ Patients with type 1 diabetes should have a dilated eye exam 5 years after diagnosis
- ▶ Patients with type 2 diabetes should have a dilated eye exam at the time of diagnosis
- ▶ Women planning to become pregnant should be warned about worsening retinopathy during pregnancy

# Microvascular Complications

## ▶ Neuropathy

- ▶ All patients with type 1 should be assessed 5 years after the diagnosis
- ▶ All patients with type 2 diabetes should be assessed starting at diagnosis
- ▶ Pharmacologic treatment is aimed at neuropathic pain
- ▶ There is no specific treatment for the underlying nerve damage other than glycemic control

# Glycemic Targets

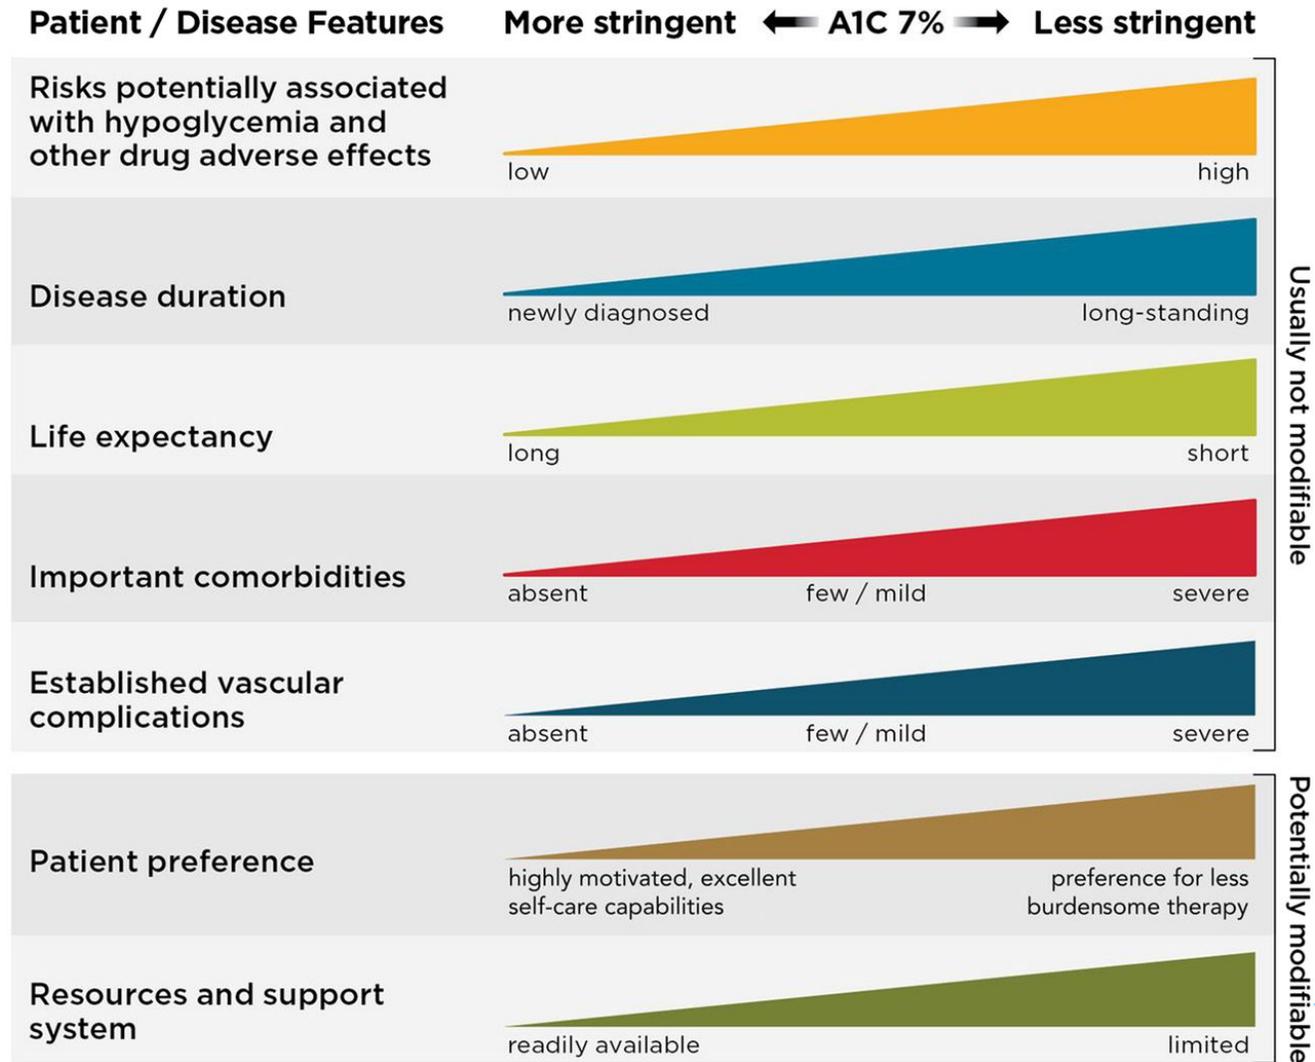

- ▶ In all patients, test A1c twice a year if they are meeting targets and quarterly if they are not on target or are starting a new therapy
- ▶ Nonpregnant adults
  - ▶ A1c < 7% is recommended
  - ▶ A1c < 6.5% is recommended for those in which it can be achieved without significant hypoglycemia or polypharmacy
  - ▶ A1c < 8% should be considered for adults with multiple microvascular and macrovascular complications and limited life expectancy

# Glycemic Targets

- ▶ Older adults
  - ▶ A1c < 7.5% is recommended for adults age 65 or older who are otherwise healthy with few coexisting chronic illnesses and intact cognition
  - ▶ A1c < 8.0 - 8.5% is recommended for those with multiple coexisting chronic illnesses, cognitive impairment, or functional dependence
  - ▶ Simplification of complex regimens is recommended

# Depicted are patient and disease factors used to determine optimal A1C targets

## Approach to Individualization of Glycemic Targets

# Pharmacologic Approaches

- ▶ Therapy for patients with type 1 diabetes is insulin
  - ▶ 0.4 to 1.0 units/kg/day is usually the requirement
    - ▶ Half is given as basal and half as premeal insulin
  - ▶ Higher doses are needed during puberty, pregnancy, and medical illness
  - ▶ Pump therapy can help reduce A1c slightly
  - ▶ Patients on pump therapy should be continued on it regardless of age
  - ▶ Continuous glucose sensor can help reduce the rate of nocturnal hypoglycemia
  - ▶ Noninsulin treatments include pramlintide

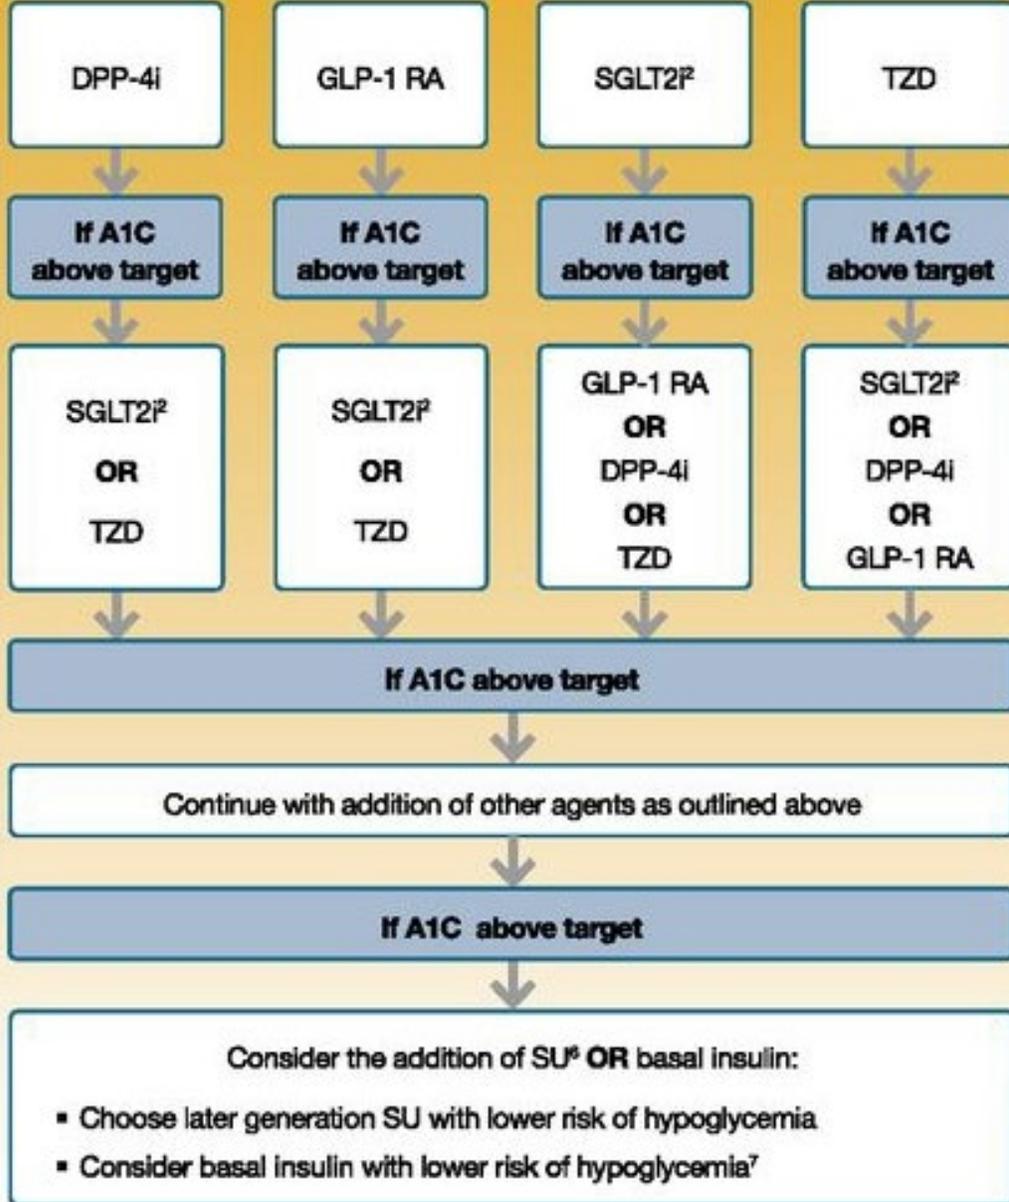

# Pharmacologic Approaches for Patients with Type 2 Diabetes

- ▶ Metformin is the preferred initial treatment
  - ▶ Should be continued for as long as tolerated
  - ▶ Recommend periodic measurement of B12 as long term treatment may be associated with B12 deficiency
- ▶ Consider introducing insulin early if there is evidence of catabolism or when hyperglycemia is severe ( $A1c \geq 10\%$ )
  - ▶ Simplify treatment once glucose toxicity resolves
- ▶ When  $A1c$  is  $\geq 1.5\%$  above glycemic target dual combination therapy is often required

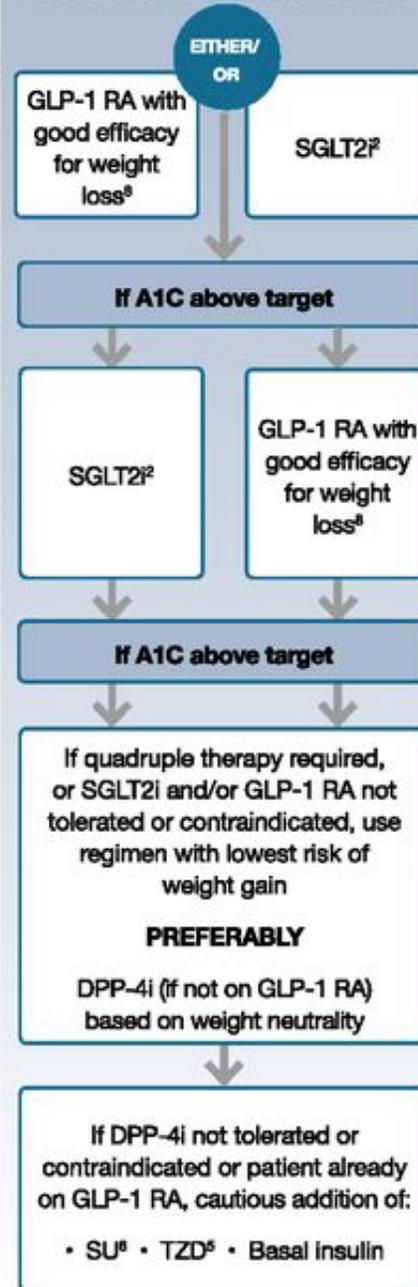

# Pharmacologic Approaches for Patients with Type 2 Diabetes

- ▶ If the A1c target is not achieved at 3 months in a patient without ASCVD or CKD, consider adding a second agent
  - ▶ Choice of agent is based on drug specific effect and patient factors
    - ▶ Cost
    - ▶ Side effects
    - ▶ Avoidance of hypoglycemia
    - ▶ Promote weight loss

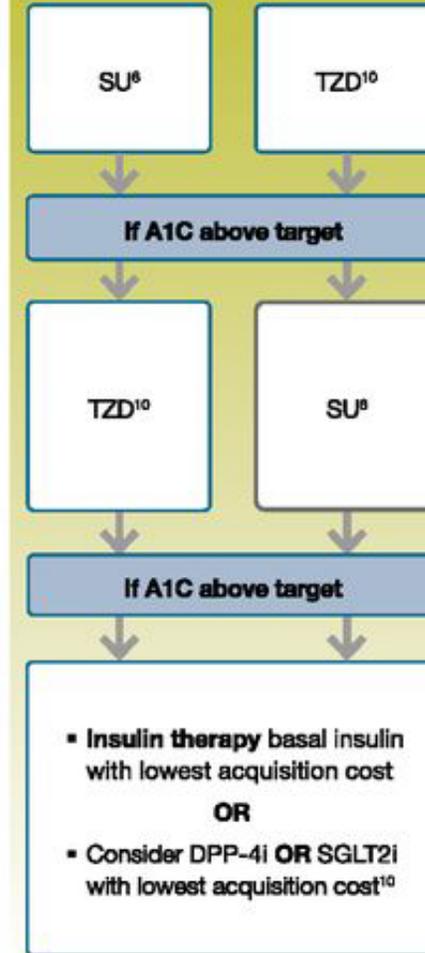

## COMPELLING NEED TO MINIMIZE HYPOGLYCEMIA

## COMPELLING NEED TO MINIMIZE WEIGHT GAIN OR PROMOTE WEIGHT LOSS

## COST IS A MAJOR ISSUE<sup>9-10</sup>

## ASCVD PREDOMINATES

- Established ASCVD
- Indicators of high ASCVD risk (age  $\geq 55$  years with coronary, carotid or lower extremity artery stenosis  $>50\%$ , or LVH)

### PREFERABLY

GLP-1 RA with proven CVD benefit<sup>1</sup>

OR

SGLT2i with proven CVD benefit<sup>1</sup>  
if eGFR adequate<sup>2</sup>

If A1C above target

If further intensification is required or patient is now unable to tolerate GLP-1 RA and/or SGLT2i, choose agents demonstrating CV safety:

- For patients on a GLP-1 RA, consider adding SGLT2i with proven CVD benefit<sup>1</sup>
- DPP-4i if not on GLP-1 RA
- Basal insulin<sup>4</sup>
- TZD<sup>5</sup>
- SU<sup>6</sup>

## HF OR CKD PREDOMINATES

- Particularly HFrEF (LVEF  $<45\%$ )
- CKD: Specifically eGFR 30-60 mL/min/1.73 m<sup>2</sup> or UACR  $>30$  mg/g, particularly UACR  $>300$  mg/g

### PREFERABLY

SGLT2i with evidence of reducing HF and/or CKD progression in CVOTs if eGFR adequate<sup>3</sup>

OR

If SGLT2i not tolerated or contraindicated or if eGFR less than adequate<sup>2</sup> add GLP-1 RA with proven CVD benefit<sup>1</sup>

If A1C above target

▪ Avoid TZD in the setting of HF  
Choose agents demonstrating CV safety:

- For patients on a SGLT2i, consider adding GLP-1 RA with proven CVD benefit<sup>1</sup>
- DPP-4i (not saxagliptin) in the setting of HF (if not on GLP-1 RA)
- Basal insulin<sup>4</sup>
- SU<sup>6</sup>

# Escalating Therapy in Patients with High Risk for or Established ASCVD, CKD, or HF

- ▶ GLP-1 receptor agonists with proven benefit: liraglutide  $>$  semaglutide  $>$  exenatide
- ▶ SGLT2 inhibitor agents with evidence of reducing HF or CKD in cardiovascular outcome trials: empagliflozin, canagliflozin, and dapagliflozin

# Initiating Injectable Therapy

- ▶ Trials which compared adding insulin versus adding a GLP-1 receptor agonist showed that the efficacy in lowering A1c was similar
- ▶ GLP-1 receptor agonists had lower risk of hypoglycemia and promoted weight loss
- ▶ GLP-1 receptor agonists are the preferred option for patients requiring injectable therapy

# Insulin

- ▶ The utility and importance of insulin as disease progresses should be explained to patients
- ▶ Self-titration based on self-monitoring should be encouraged and it usually leads to better compliance and thus outcomes
- ▶ Basal insulin can be started at 0.1-0.2 units/kg/day or at 10 units per day and titrated every 3 days or so as needed
  - ▶ NPH as well as U-100 glargine or detemir can be used to achieve fasting targets
  - ▶ Longer acting insulins such as Tresiba (Degludec) or Toujeo (U-300 glargine) have lower risk of hypoglycemia

# Insulin

- ▶ Keep in mind that newer and longer acting insulins are more expensive
- ▶ Prandial insulin should be given before meals, starting dose can be 4 units or 10% of basal dose at each meal time
- ▶ Combination therapy with human Regular insulin, NPH insulin, and 70/30 NPH/Regular insulin products is more cost effective
  - ▶ Trials comparing human Regular insulin with rapid-acting analogs have not found significant differences in A1c or hypoglycemia

# Acknowledgments
